Contents

Executive Summary	191
1 Current performance of the Belle detector	193
1.1 Beampipe and beam background	193
1.1.1 Synchrotron Radiation Background	193
1.1.2 Particle Background	197
1.1.3 SVD2 Beampipe: Design and Status	198
1.2 Silicon Vertex Detector (SVD)	205
1.3 Central Drift Chamber (CDC)	210
1.4 Particle Identifier	212
1.4.1 Framework	212
1.4.2 Present K/π Separation Performance	212
1.4.3 Disadvantages of the Present PID System	213
1.4.4 Background situation	214
1.5 Electromagnetic calorimeter ECL	216
1.5.1 Performance	216
1.5.2 Effect of Background	218
1.6 KLM	225
1.7 Trigger and DAQ system	230
1.7.1 Trigger	230
1.7.2 Data Acquisition System	232
1.8 Computing System	235
1.8.1 KEK B-computing system	235
1.8.2 Data flow	235
1.8.3 PC farms	236
1.8.4 Network	236
2 Considerations for the detector at SuperKEKB	238
2.1 Expected background conditions	238
2.2 Guideline	239
2.3 Strategy for tracking/vertexing	240
2.3.1 Degradation of tracking	240
2.3.2 Chamber gas charge up	240
2.3.3 Dead time of the readout electronics	240
2.3.4 Degradation of the vertex resolution	244
2.3.5 Strategy	245
2.4 Strategy for Calorimetry	247
2.4.1 Improvement of calorimeter performance	247

2.4.2	Signal hit reconstruction	248
2.4.3	Pure CsI for the endcap	249
2.5	Requirements for Particle Identifier	254
2.5.1	Impact of PID Improvement on Physics Reach	254
2.6	DAQ requirements	258
3	SuperBelle at SuperKEKB	259
3.1	Beampipe and expected beam background for Super-KEKB	259
3.2	Vertex Detector	261
3.2.1	Overview of VTX for SuperKEKB	261
3.2.2	Innermost Layer	262
3.2.3	Readout Electronics	267
3.2.4	Performance	269
3.3	Central Tracker	271
3.4	Particle Identifier	274
3.4.1	Overview	274
3.4.2	TOP counter (barrel)	274
3.4.3	Aerogel Ring Imaging Čerenkov Counter (endcap)	282
3.4.4	Other possibilities	294
3.5	Calorimeter	303
3.5.1	Upgrade plan	303
3.5.2	Study of the Belle CsI calorimeter prototype with BINP tagged photon beam	304
3.6	KLM	310
3.6.1	RPC option for the KLM endcap	310
3.6.2	Scintillator option for the KLM endcap	310
3.6.3	Performance	316
3.6.4	Conclusions	319
3.7	Trigger/DAQ system	321
3.7.1	Overview	321
3.7.2	Trigger	322
3.7.3	Trigger Timing Distribution	322
3.7.4	Readout Subsystem	322
3.7.5	Event Building and Level 3 Trigger Farms	324
3.7.6	Event Reduction	324
3.8	Computing	328
3.8.1	Requirements for computing at Super KEKB	328
3.8.2	Storage system	329
3.8.3	CPU	329
3.8.4	Computing model	330
3.8.5	Data bookkeeping and management	330
3.8.6	Regional centers	331
3.8.7	Skims for physics analysis	332
3.8.8	Facilities	332
3.8.9	Software	332
3.8.10	Plan	332

Executive Summary

For the upgrade of the Belle detector in the SuperKEKB project, the first consideration is to maintain the current performance in the very harsh background environment due to the high beam current. The performance of the Belle detector is summarized in the next chapter. To evaluate the possible degradation of the performance due to the extremely high background, we extrapolate the observed background to a level 20 times higher taking the nature of the components of background properly into account.

In the view of vertexing, the silicon micro-strip detector with a shaping time 5 times shorter ($1\mu\text{sec}$ to 200nsec) and a strip length 6 times shorter for the inner layers can have 1/30 of the present occupancy. This may imply that the innermost layer can move even closer to the interaction point than the present one (1.5cm) without any loss of vertexing performance. To obtain a robust tracking for low momentum particles, the silicon tracker will be extended out to radius of 15 cm. As for tracking, we can easily reduce the hit loss rate due to overlapping of background by making the time constant in the electronics shorter. Further reduction can be accomplished with the drift cells of half the present size. Simulation studies with overlays of real background taken under current beam conditions show that the degradation of the tracking efficiency for high momentum particles would be small ($0.91\rightarrow 0.90$) even with 10 times more background. Here a factor of two is included to account for the smaller cell size. The degradation of efficiency for low momentum particles is somewhat larger, $0.94\rightarrow 0.85$. We believe we can restore this rather significant loss for low momentum particles by the special reconstruction code currently under development.

On the other hand, the present background level observed in the end-cap part (EECL and EKLM) is rather serious and an upgrade to another advanced technology is necessary. Among several candidates pure CsI crystals with photo tetrode readout is the most promising for the EECL. Bars or tiles of plastic scintillator with a silicon photo multipliers (SiPM) are a good candidate for the replacement of the RPC technology used in the EKLM.

For a particle identification device, the upgrade will be undertaken not only for higher tolerance against background but also for much better K/π discrimination in the momentum range up to $4\text{ GeV}/c$. Reduction of material in front of the calorimeter and allocation of more tracking volume to CDC is also planned. Among several options to be discussed in the later chapter, the DIRC technology with the Time of Propagation (TOP) scheme is a good candidate for the barrel part while RICH technology with aerogel radiator is considered for the end-cap one. For either option, the development of novel photon detectors with timing resolution better than 100psec , sensitivity as low as a single photon level and an imaging capability are needed. The intense R&D work on these is underway. The current plan for the detector configuration is summarized in Fig. 1.

The trigger and data acquisition systems should also be upgraded to handle the 20 times higher occupancy level due to the higher beam current. The DAQ system will be using a pipelined readout scheme in order to cope with the high trigger rate, more than 10kHz, with

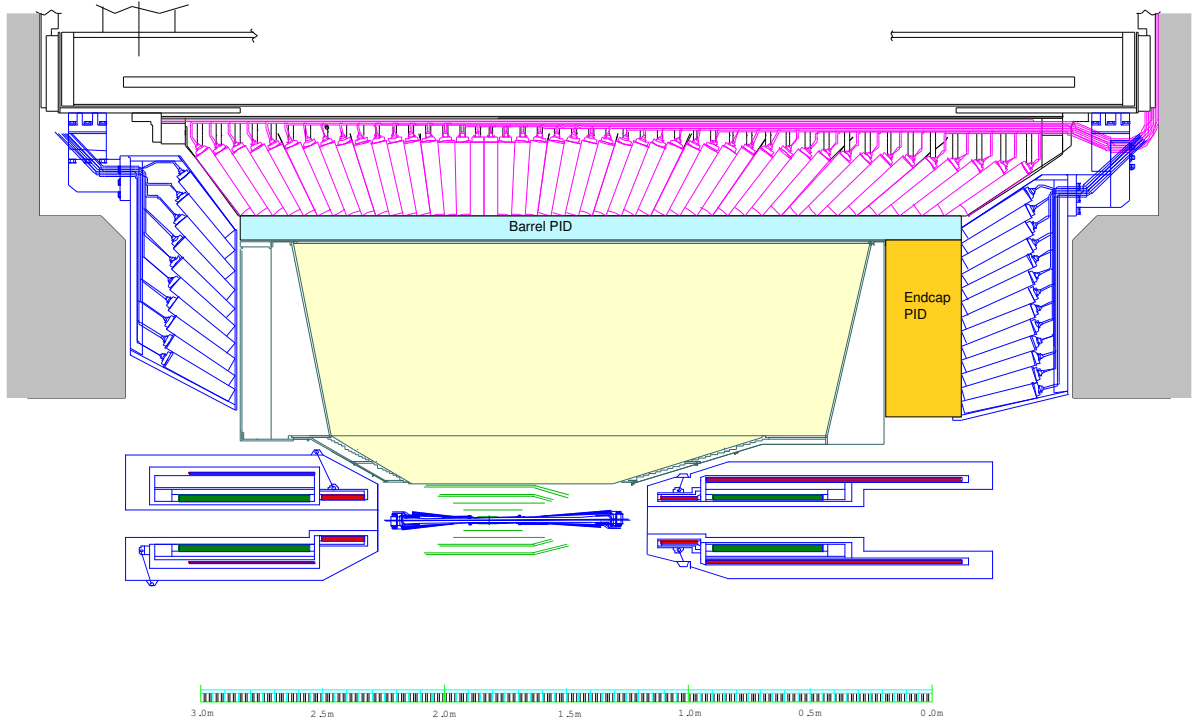

Figure 1: The conceptual illustration of the upgraded Belle.

a low dead time. A readout subsystem consists of a set of modularized common readout platforms called COPPER. They are also modularized and implemented as daughter cards (called as FINNESE) which can be implemented according to various requirements of the detector subsystem. The modules are equipped with a L1 pipeline FIFO so as to record the digitized signal without a readout dead time.

The computing at SuperKEKB is another technological challenge. The online data have to be recorded at a speed of 250 MB/sec after online reconstruction and reduction amounting to the data size of 5 PB/year. Considering the demands from the event skimming and Monte Carlo simulations, we will need a storage system holding 10~20 PB at the beginning of SuperKEKB, and it should be expandable up to several tens of PB as we take more data. Vast expanding demands are also anticipated in the CPU power and other resources. The GRID technology to be applied in the LHC experiments could be a solution.
